Using NetBeans with EJB

Graham White

February 2017

This lab is about setting up Netbeans together with its Enterprise Java Beans support (Glassfish). Netbeans is already installed in the lab, but we need also Glassfish, which isn't installed (this situation may change). So, if you are in the ITL, this is the way it works (and you can get a similar installation on your laptop, though you will have to install the *Java EE version* of netbeans first).

We will be using the Java EE and Java Web Learning trail, which you can find here `https://netbeans.org/kb/trails/java-ee.html` We start with this `https://netbeans.org/kb/docs/web/quickstart-webapps.html`, which might be a bit elementary, but which introduces you to the tools. You create a new Web Application project, and then when it asks you for the server location you click on the New Server button, and then choose Glass Fish; you click on the download button, and it will end up in your filespace. Having got Glass Fish installed, you can then continue with the instructions.

After you've done that example, you can continue with the rest of the tutorials in Getting Started, which will introduce you to the EJB basics.
